

Amendments to the Specification:

Please replace the paragraphs at page 4, line 5 – page 5, line 2 with the following rewritten paragraphs:

A signature key is denoted by (x, α, p) and a verification key is denoted by (y, α, p) , (y, γ, p) wherein p denotes a prime number and α denotes and γ denotes a positive constant smaller than p . These integers are in relation represented by the equation (1)

[Equation 1]

$$(1) \quad y = \alpha^x (\text{mod } p) \quad y = \gamma^x (\text{mod } p)$$

Calculation of the private integer x from the public integer y is a discrete logarithm problem, and it is difficult to get x by means of calculation if p is sufficiently large (500 bits or larger).

A prover generates a random number k which is mutually prime to $p-1$, and calculates a signature for a message m by use of the equations (2) and (3).

[Equation 2]

$$(2) \quad r = \alpha^k (\text{mod } p) \quad r = \gamma^k (\text{mod } p)$$

[Equation 3]

$$(3) \quad s = (h(m) - xr) k^{-1} (\text{mod } p-1)$$

wherein h denotes a one-way hash function. A prover sends the message m and signature (r, s) to a verification side.

The verifier receives m and (r, s) , and checks whether the equation (4) holds.

[Equation 4]

$$(4) \quad \alpha^{h(m)} = y^r r^s (\text{mod } p) \quad \gamma^{h(m)} = \gamma^r r^s (\text{mod } p)$$

If the equation holds, then it is proved that m is a message prepared by the prover.
